Why EFT?

(we think) Every theory is an effective theory!

Reductionism: (还原论)

A more fundamental theory will appear at

a higher energy
smaller length scale.

The more correct way to ask
“物质是否无限可分”

(natural units: 1 unit $[E] \sim [L]^{-1}$)

(or maybe there is an ultimate theory?)

Quantum gravity \Leftrightarrow space time quantized?
notion of energy distance breaks down?

Not everyone believes Reductionism...

Key ingredient: **locality** (many definitions, here it means)

Measurements at large distance
low energy should not be

sensitive to the physics at small distance
high energy

Engineers don't need to learn QFT to build bridges!
car

classical Mechanics is replaced by QFT ^{QM} _{Relativity} at small scale
high energy

does not mean it's wrong, it's an effective theory

at large scale
low energy

- Even if we know the more fundamental theory (e.g. QFT), it can be more convenient to use an EFT (e.g. classical Mech.) at low energy!

example 1 Multipole Expansion in Electrostatics

\vec{r} . $V(\vec{r})$
electric potential

locality: For $r \gg a$, this looks like a point charge!

$$V(\vec{r}) = \frac{1}{r} \sum_{l,m} b_{lm} \frac{1}{r^l} \underbrace{Y_{lm}(\theta, \varphi)}_{\text{spherical harmonics (球面波函数)}} \quad (\text{kind of like operators in field theory})$$

$$= \frac{1}{r} \sum_{\substack{l,m \\ = 0, 1, \dots}} c_{lm} \left(\frac{a}{r}\right)^l Y_{lm} \quad b_{lm} \equiv c_{lm} a^l$$

c_{lm} s are dimensionless parameters (usually of order 1).

separation of scales ($\frac{a}{r} \ll 1$) \Rightarrow The expansion is useful,

i.e. we only need to keep a few terms
in the l expansion to get a good approximation
(more terms \Rightarrow better accuracy)

distance

IR

r

UV

a

expansion
parameter

$\frac{a}{r}$

$E \sim 1/r$

collider energy
or
EW scale \checkmark

$\Lambda \sim 1/a$

scale of
new physics

$\frac{E}{\Lambda}$

(or $\frac{v}{\Lambda}$)

$c_i^{(n)}$ — dim- n operator

- There is no precise definition of a . One could only measure the combination $b_{lm} = c_{lm} a^l$. $\left(\frac{c_i^{(n)}}{\Lambda^{n-4}}\right)$

- If we know the charge distribution, we can do the expansion to find out all the $b_{lm}(c_{lm})$. This is called matching. (top down) (UV theory)

- If we don't know \dots , we can treat all C_m 's as free parameters and try to measure them experimentally. (bottom up)

After truncating the series (throwing away terms with $l > l_{\max}$) there are a finite number of parameters.

If we make enough measurements we can constrain all parameters. (C_m)

- To precisely determine the values of C_m we can either
 - make very precise measurement at large r (low energy)
 - make measurements at small r (high energy)

energy vs. precision (or both!)

Important aspects for colliders.

If $r \approx a$, the expansion breaks down!

High energy is always good, but EFT may not be valid!

multiple scales

$\rightarrow r$.

$r \gg a \gg d$

($\Lambda_{EW} \ll \Lambda_{SUSY} \ll \Lambda_{GUT}$)

example 2 Fermi's theory

muon decay

$$i\mathcal{M} = \left(\frac{-ig}{\sqrt{2}}\right)^2 (\bar{\nu}_\mu \gamma^\mu \mu_L) (\bar{e}_L \gamma^\nu \nu_e) \cdot \frac{-ig_{\mu\nu}}{p^2 - M_W^2}$$

(ignore w width since $p^2 \ll M_W^2$)

For $p^2 \ll M_W^2$, we can expand the operator

$$\frac{1}{p^2 - M_W^2} = -\frac{1}{M_W^2} \left(1 + \frac{p^2}{M_W^2} + \frac{p^4}{M_W^4} + \dots\right)$$

keeping only the 1st term we have

$$i\mathcal{M} = \frac{-ig^2}{2M_W^2} (\bar{\nu}_\mu \gamma^\mu \mu_L) (\bar{e}_L \gamma_\mu \nu_e) + \mathcal{O}\left(\frac{1}{M_W^4}\right)$$

4-fermion
contact interaction

which can be produced by the local Lagrangian

often written as $\frac{G}{\Lambda^2}$ where $\Lambda \sim M_W$, if the UV theory is unknown.

$$\mathcal{L} = -\frac{g^2}{2M_W^2} (\bar{\nu}_\mu \gamma^\mu \mu_L) (\bar{e}_L \gamma_\mu \nu_e) + \mathcal{O}\left(\frac{1}{M_W^4}\right)$$

dimension-6 operator, what Fermi wrote down.

If we keep more terms in the Lagrangian we'll generate higher dimensional operators, e.g. the $\frac{1}{m_W^4}$ term corresponds to dim-8 operators.

(Higher dimensional operators may look very complicated, it's actually much easier to use on-shell amplitudes!)

This is the simplest example of the **matching** between the full model (SM) and the low-energy effective field theory (Fermi's theory).

- This way of matching is called **amplitude matching**.
(Finding a EFT that gives the same low energy amplitudes as the full theory.)
- Matching can also be understood from the **path integral** picture:

consider light field(s) ϕ
heavy field(s) Φ , light

generating functional (or the 1LP effective action)

$$Z_{\text{uv}}[J_\phi, J_\Phi] = \int \mathcal{D}\phi \mathcal{D}\Phi \exp \left\{ i \int d^4x [\mathcal{L}(\phi, \Phi) + J_\phi \phi + J_\Phi \Phi] \right\}$$

at low energy, Φ cannot be excited, set $J_\Phi = 0$
"integrating out the heavy fields Φ "
literally

$$Z_{\text{EFT}}[J_\phi] = \int \mathcal{D}\phi \exp \left\{ i \int d^4x [\mathcal{L}_{\text{EFT}}(\phi) + J_\phi \phi] \right\}$$

many literature on this (Xiaochuan Lu, Zheng Kang Zheng ...)

Note: The two pictures of matching are equivalent.

back to $\frac{1}{p^2 - M_W^2} = -\frac{1}{M_W^2} \left(1 + \frac{p^2}{M_W^2} + \frac{p^4}{M_W^4} + \dots \right)$

- For $p^2 \ll M_W^2$, the 4F operator gives a very good approximation of the full theory. This is the case for muon decay. ($p^2 < m_\mu^2$ $\frac{m_\mu^2}{M_W^2} \sim 10^{-6}$)

- For $p^2 \gtrsim M_W^2$, the expansion breaks down!

consider $2 \rightarrow 2$ scattering 
for $E_{cm}^2 \sim p^2$ we'll see the resonance!

- The coefficient of the 4F operator is $-\frac{g^2}{2M_W^2} = \frac{-2}{V^2}$.

Measuring muon decay only tells us the value of V

(or $G_F \equiv \frac{1}{\sqrt{2}} V^2$), but not M_W , which depends on g .

- But M_W is the scale at which the EFT breaks down!

In our world, $g \approx 0.65$.

Suppose we've measured G_F but don't know the value of g .

The scale at which the EFT breaks down depends on the value of the coupling!

If g is $\begin{cases} \text{very small, } W, Z \text{ would be much lighter} \\ \text{very large, } \dots \dots \dots \text{ heavier.} \end{cases}$
cutoff \wedge 没有下限
 有上限

but if $g \gtrsim 4\pi$, the theory becomes non-perturbative! $\Lambda_{max} \sim \frac{1}{2} 4\pi \cdot 246 \text{ GeV} \approx 1.5 \text{ TeV}$

- perturbative unitarity bound

$$2 \rightarrow 2 \text{ scattering} \quad \text{dim-6} \quad 4f \text{ operator} \quad \times \quad \frac{-g^2}{2M_W^2} \quad M \sim E^2$$

unitarity bound is violated for $\sqrt{s} \gtrsim 1.5 \text{ TeV}$

corresponds to the value of M_W with $g \sim 4\pi$!

This is the scale at which the EFT has to break down.
(but for weakly coupled theory the EFT would break down at a lower scale.)

- unitarity is violated X

- perturbative (EFT) expansion breaks down ✓

each term in the expansion is much larger than the sum.

- In this simple example, if we also measure the dim-8 coefficient ($\sim \frac{g^2}{M_W^4}$) we can derive the W mass.

In more complicated cases (with multiple heavy particles) it is in general not possible.

- global from

example 3 a complex scalar EFT

(with a $U(1)$ global symmetry)

- bottom up approach, writing down all operators in the EFT approach.

$$\mathcal{L} = \partial_\mu \phi^* \partial^\mu \phi - m^2 |\phi|^2 - \frac{\lambda}{4} |\phi|^4 \quad [\mathcal{L}] \leq 4$$

$$+ \sum_i \left(\frac{C_i^{(5)}}{\Lambda} \right) \mathcal{O}_i^{(5)} + \sum_i \left(\frac{C_i^{(6)}}{\Lambda^2} \right) \mathcal{O}_i^{(6)} + \sum_i \left(\frac{C_i^{(7)}}{\Lambda^3} \right) \mathcal{O}_i^{(7)} + \dots$$

has dimension $4-n$

$$[\mathcal{L}] = 4, \quad [\mathcal{O}^{(n)}] = n, \quad [\mathcal{L}] = 0, \quad [\Lambda] = 1$$

Λ ~ scale of the new physics (mass of the new particles)

Large $\Lambda \Rightarrow$ The EFT expansion is good.

Operators in \mathcal{L} are divided into 3 classes based on their mass dimensions

(coupling dimension)

$[O] < 4$ relevant > 0 $|\phi|^2$

$[O] = 4$ marginal $= 0$ $|\phi|^4$

$[O] > 4$ irrelevant < 0

$$M \sim \left(\frac{E}{\Lambda} \right)^{n-4}$$

Small effects at low energy

EFT breaks down at high energy! With $[O] > 4$, the theory cannot be a complete theory \Rightarrow why it's called an EFT.

This classification is also related to renormalizability — we'll come back to it later.

Now let's try to write down the higher dim. operators...

Each $O_i^{(n)}$ need to be invariant under Lorentz $U(1)$ symmetry.

No odd dimension operator!

$\phi^* \phi \phi^* \partial_\mu \phi$ not Lorentz invariant

$|\phi|^4 \phi$ not $U(1)$ invariant

Large $\Lambda \Rightarrow$ leading contribution: $\mathcal{O}_i^{(6)}$!

Bottom-up approach: write down all possible $\mathcal{O}_i^{(6)}$!

Not all of them are independent!

Operator redundancy

Operators are related by

- Integration by parts (IBP)
- Equation of Motion (EOM) ← why EOM works beyond the classical level
- Fierz identity... (no use for scalar theory)
- (more generally, field redefinition)

Let's try to write down all possible d6 operators:

0 ∂ : $|\phi|^6$

2 ∂ : $(\partial^\mu \phi^* \partial_\mu \phi) \phi^* \phi, \underbrace{(\partial^\mu \partial_\mu \phi^*) \phi \phi^* \phi, ((\partial^\mu \phi^*) \phi)^2}_{+ \text{ h.c. }}, \dots$

4 ∂ : $\underbrace{(\partial^\mu \partial_\mu \phi^*)(\partial^\nu \partial_\nu \phi), \dots}_{\text{only 1 indep operator}}$

only 1 indep operator
 \Rightarrow

LBP: total derivative

$$(\partial^\mu \partial_\mu \phi^*)(\partial^\nu \partial_\nu \phi) = \underbrace{\partial^\mu [(\partial_\mu \phi^*)(\partial^\nu \partial_\nu \phi)]}_{\text{moved } \partial^\mu \text{ here, equivalent operator}} - \partial_\mu \phi^* \partial^\mu \partial^\nu \partial_\nu \phi$$

ECM:

$$\frac{\partial \mathcal{L}}{\partial \phi} - \partial_\mu \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi)} = 0 \quad (\phi \leftrightarrow \phi^*)$$

$$-m^2 \phi^* - \frac{\lambda}{2} \phi^* \phi^* \phi - \partial_\mu \partial^\mu \phi^* + \underbrace{\dots}_{d \geq 5} = 0$$

$$\partial_\mu \partial^\mu \phi^* = -m^2 \phi^* - \frac{\lambda}{2} \phi^* \phi^* \phi + \underbrace{\dots}_{d \geq 5}$$

$$\partial_\mu \partial^\mu \phi = -m^2 \phi - \frac{\lambda}{2} \phi \phi \phi^* + \dots$$

$$\frac{c}{\Lambda^2} (\partial^\mu \partial_\mu \phi^*) \phi \phi^* \phi$$

absorb in a redefinition of λ

$$= -\frac{c}{\Lambda^2} m^2 |\phi|^4 - \frac{c}{\Lambda^2} \frac{\lambda}{2} |\phi|^6 + \dots$$

things get more complicated if we go beyond $d=6$!

$d \geq 8$, ignore

We can eliminate $(\partial^\mu \partial_\mu \phi^*) \phi \phi^* \phi$ in favor of $|\phi|^6$
 $(\partial^\mu \partial_\mu \phi^*)(\partial^\nu \partial_\nu \phi)$

total derivative

$$\begin{aligned} & \partial^n ((\partial_n \phi^*) \phi \phi^* \phi) \\ &= (\partial^n \partial_n \phi^*) \phi \phi^* \phi + 2 (\partial_n \phi^* \partial^n \phi) \phi^* \phi \\ & \quad + \underbrace{((\partial_n \phi^*) \phi)^2}_{\text{can eliminate}} + \cancel{(\partial_n \phi^*) \phi \phi^* (\partial^n \phi)} \end{aligned}$$

2 independent d6 operators!

We can choose $|\phi|^6$, $|\phi|^2 \partial_n \phi^* \partial^n \phi$.

This is called choosing a basis. (choose which redundant operators to eliminate)
Of course we can choose a different basis.

Why not just keep redundant operators? \swarrow convenience
 \searrow global fit

(important to know how many indep. physical parameters we have)

★ Physics are basis-independent.

Physicists are basis-dependent!

HEFT workshop
2019

Instead of e.o.m. we can perform field redefinition...

$$\mathcal{L} = \partial_\mu \phi^* \partial^\mu \phi - m^2 |\phi|^2 - \frac{\lambda}{4} |\phi|^4$$

$$+ \frac{C_1}{\Lambda^2} |\phi|^6 + \frac{C_2}{\Lambda^2} |\phi|^2 \partial_\mu \phi^* \partial^\mu \phi$$

$$+ \left(\frac{C_3}{\Lambda^2} (\partial^\mu \partial_\mu \phi^*) \phi \phi^* \phi + \text{h.c.} \right) + \frac{C_4}{\Lambda^2} (\partial^\mu \partial_\mu \phi^*) (\partial^\nu \partial_\nu \phi)$$

Field redefinition choose α_1, α_2 to cancel

$$\phi \rightarrow \phi + \alpha_1 \frac{\phi^* \phi \phi}{\Lambda^2} + \alpha_2 \frac{\partial_\nu \partial^\nu \phi}{\Lambda^2} \quad \text{does not change kinetic, mass terms}$$

indep. operators \Rightarrow ^(massless) on-shell amplitude

$$[A] = 4 - n$$

$$\sim \frac{C_1}{\Lambda^2}$$

$$\sim \frac{C_2}{\Lambda^2} (s+u)$$

general:

$$\alpha s + \beta t + \gamma u \quad (s+t+u=0)$$

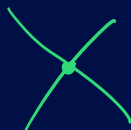

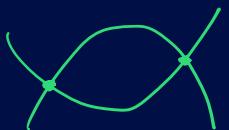

$$s \Leftrightarrow u \text{ symmetric} \Rightarrow \alpha = \gamma$$

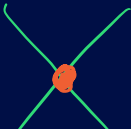

$$\text{Diagram with a cross} = \text{Diagram with a star} \quad (\partial^2 \phi)^2 \text{ cancel with propagator } (\partial^2 \phi^4)$$

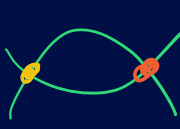

$$\frac{1}{p^2(1+\frac{p^4}{\Lambda^2})} = \frac{1}{p^2} (1 - \frac{p^2}{\Lambda^2} + \dots)$$

What about renormalizability?

Operators with $d > 4$ are non-renormalizable?

 $\sim \lambda$
  $\sim \lambda^2$
  counter term $\sim |\phi|^4$
 $|\phi|^4$
 no need to add extra terms in $\mathcal{L} \Rightarrow$ renormalizable

 $\sim \frac{C_{(6)}}{\lambda^2}$
  $\sim \frac{C_{(6)}^2}{\lambda^4}$
  counter term $d=8 \quad |\partial_\mu \phi|^4$
 $|\phi|^2 (\partial_\mu \phi^\dagger \partial^\mu \phi)$ need to add Δ many terms in $\mathcal{L} \Rightarrow$ non-re!

need to add  $\sim \frac{C_{(8)}}{\lambda^4} \Rightarrow$  $\sim \frac{C_{(6)} C_{(8)}}{\lambda^6}$

\Rightarrow need $d=10$ counter term! - - - - -

or  $\sim \frac{C_{(6)}^3}{\lambda^6} \Rightarrow$ need $d=10$ counter term!

correct argument: We only work up to a fixed order in the EFT expansion and discard all higher order terms

up to $d=6$: keep   $\sim \frac{1}{\lambda^2}$ counter term also $d=6$
 (2 loops)
 discard  , ... $\sim \frac{1}{\lambda^4}$

u/p to $\frac{1}{\Lambda^4}$: add    $\sim \frac{1}{\Lambda^4}$

discard  $\dots \frac{1}{\Lambda^6}$

★ EFT is renormalizable order by order in the EFT expansion.

why SMEFT?

SM is incomplete $\left(\begin{array}{l} \text{gravity,} \\ \text{dark matter, matter anti-matter asymmetry} \end{array} \right)$

There must be BSM New physics
but we don't know what it is. $\left(\begin{array}{l} \text{some people think} \\ \text{they know} \end{array} \right)$

light particle

very weak coupling
~~SMEFT~~

heavy particle ($M \gg v$)

SM EFT ✓

• strictly speaking, graviton makes SMEFT invalid.

(But that's ok....)

— since we don't know what it is

- bottom-up approach: Be agnostic about the UV physics and try to systematically parameterize its effects at low energies.
by writing down higher dimension operators. (top-down: model building....)
- useful even if we know the UV model for calculation....
resumming large logs with RG...

SM EFT

$$\mathcal{L}_{\text{SM EFT}} = \mathcal{L}_{\text{SM}} + \sum_i \frac{C_i^{(5)}}{\Lambda} \mathcal{O}_i^{(5)} + \sum_i \frac{C_i^{(6)}}{\Lambda^2} \mathcal{O}_i^{(6)} + \sum_i \frac{C_i^{(7)}}{\Lambda^3} \mathcal{O}_i^{(7)} + \dots$$

~~$$[\mathcal{L}] = 4, \quad [\mathcal{O}^{(n)}] = n, \quad [\Lambda] = 1$$~~

Note: each \mathcal{O}_i needs to be invariant under Lorentz and gauge transformations $SU(3) \times SU(2) \times U(1)$

non-decoupling physics

HEFT: only $SU(3) \times U(1)$ (linear vs. non-linear...)

bottom up approach: write down all possible operators!
(not all operators are independent...)

dim 5: only 1 type of operators $\sim LLHH$ (Weinberg operator)

HW: write down the exact form of the Weinberg operator
neutrino majorana mass

$$\mathcal{L} \sim \frac{C}{\Lambda} LLHH \rightarrow C \frac{v^2}{\Lambda} \nu\nu \quad \left. \begin{array}{l} C \sim 1 \\ \Lambda \sim \Lambda_{\text{GUT}} \end{array} \right\} \Rightarrow m_\nu \sim 10^{-2} \text{eV}$$

Seesaw mechanism: large $\Lambda \Rightarrow$ naturally explains why m_ν is small!

several possible UV completions: type I, II, III, ... 

Further more, all odd dimension operators violate Baryon (B) or Lepton (L) numbers.

B, L, charge of $U(1)_B$, $U(1)_L$ global symmetry

	B	L
q	$\frac{1}{3}$	0
\bar{q}	$-\frac{1}{3}$	0
l	0	1
\bar{l}	0	-1

$B \neq$ effects are usually strongly constrained (e.g. proton decay).

Assuming B, L are conserved around the TeV scale

$$\mathcal{L}_{\text{SMEFT}} = \mathcal{L}_{\text{SM}} + \sum_i \frac{C_i^{(6)}}{\Lambda^2} \mathcal{O}_i^{(6)} + \sum_i \frac{C_i^{(8)}}{\Lambda^2} \mathcal{O}_i^{(8)} + \dots$$

How many independent parameters do we have? ($B \& L$ conserved)

& (quartic GC) aQGC 

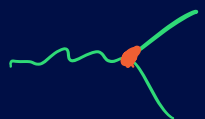

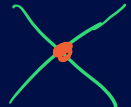

2) $\varphi \rightarrow H$ $|H|^6 \rightarrow$  h^3 modifies h^3 & h^4
couplings
 $(\partial|H|^2)^2$ modify $\partial_\mu h \partial^\mu h$, h wave function renormalization
shift Higgs couplings

3) $\psi^2 \varphi^3 \rightarrow$ modify Yukawa coupling
(relation between m & y) 

4) $|H|^2 V_{\mu\nu} V^{\mu\nu}$ $\begin{cases} h V_{\mu\nu} V^{\mu\nu} \\ hh V_{\mu\nu} V^{\mu\nu} \end{cases}$ 

different from $h Z^\mu Z_\mu$ $h W^\mu W_\mu$

5) $H \rightarrow \nu$ dipole  real magnetic
imaginary electric

6) $H \rightarrow \nu$  \Leftrightarrow  7) $4f$ interaction
modifies SM V_{ff} coupling contact interaction 

1 generation:

59 operators $\begin{cases} 17 \text{ non hermitian} \Rightarrow \text{complex coefficient} \\ 42 \text{ hermitian} \Rightarrow \text{real coefficient} \end{cases}$

$$42 + 17 \times 2 = 76 \text{ parameters}$$

3 generations: 2499 parameters!

(many of them are 4f operators)

In other bases, we sometimes keep operators with more derivatives.

e.g. $\mathcal{O}_{2W} = -\frac{1}{2} (D^\mu W_{\mu\nu}^a)^2$ $\mathcal{O}_{2B} = -\frac{1}{2} (\partial^\mu B_{\mu\nu})^2$

useful in describing universal contributions to 4f interactions.

$$\mathcal{O}_{HW} = ig (D^\mu H)^\dagger \sigma^a (D^\nu H) W_{\mu\nu}^a$$

$$\mathcal{O}_{HB} = ig' (D^\mu H)^\dagger \underbrace{(D^\nu H)}_{\text{(longitudinal)}} B_{\mu\nu}$$

useful for describing \checkmark anomalous triple gauge couplings (aTGCs)

RG running

1308.2627

1310.4838

1312.2014

Alonso, Jenkins, Manohar, Trutt

running couplings \Leftrightarrow resum large logs

tree level calculation + running couplings give
a reasonably accurate prediction.

suppose $v \rightarrow 0$, $[g_{sm}] = 0$

$$\text{let } C_i^{(6)} = \frac{L_i^{(6)}}{\Lambda^2} \quad [C_i] = -2$$

$$\text{d6 RGE } \beta_{C_i} \equiv \mu \frac{d}{d\mu} C_i = \gamma_{ij} C_j \quad \leftarrow \text{still holds!}$$

\uparrow
anomalous dimension matrix
depends on g_{sm}

This is the only form allowed by dimensional analysis!

How about $v \neq 0$?

$$C_i \text{ contribute to } \beta_{g_{sm}} = \mu \frac{d}{d\mu} g_{sm} = \dots + \gamma_i^{2-2} v^2 C_i g_{sm} + \dots$$

$$C_i^2 \quad C_i^{(8)} \text{ contribute to } \beta_{C_i}$$

$d6^2 \quad d8 \leftarrow$ can ignore since they are higher order

($d8$ RGEs are more complicated, has both $d8$ & $d6^2$ contributions)

Solve RGE. If expand to 1st loop order (not resummed)

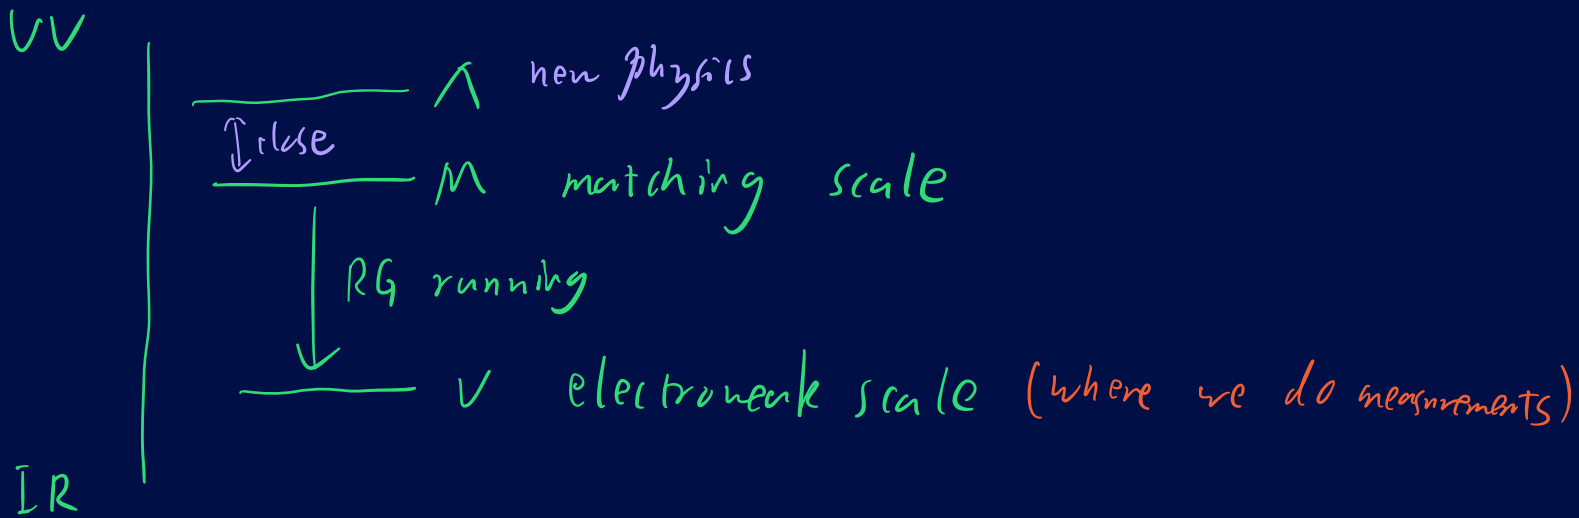

$$C_i(\mu) = C_i(\mu_0) + \log \frac{\mu}{\mu_0} \gamma_{ij} C_j$$

note:
important to
resum!

generally solve
numerically.

RGE implies:
 — running
 — mixing (off-diagonal terms in γ_{ij})

Matching & Running

mixing: Operators not generated at matching scale can be generated at a lower scale via running!

running effects can be significant if $V \ll \Lambda$!!
more conveniently calculated in the EFT.

See examples in Manohar & Skiba's lecture notes,

Schwartz §1.3

RGE \Rightarrow on-shell amplitude see e.g. 1505.01844
Cheung & Shen

Phenomenology

$$\mathcal{L}_{\text{SMEFT}} \xrightarrow{\text{amplitude}} \mathcal{M} \xrightarrow{\text{observable}} \frac{d\sigma}{d\Omega}, \frac{dP}{d\Omega}$$

expand in terms of $\frac{1}{\Lambda}$

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \mathcal{L}_6 + \mathcal{L}_8 + \dots$$

$$m \quad q\bar{q} \rightarrow l^+l^-$$

$$+ \text{diagram with } d6 \text{ at vertex 1} + \text{diagram with } d6 \text{ at vertex 2} + \text{diagram with } d6 \text{ at crossing} + \dots \quad \frac{1}{\Lambda^2}$$

$$+ \text{diagram with } d6^2 \text{ at two vertices} + \text{diagram with } d8 \text{ at vertex 1} + \text{diagram with } d8 \text{ at vertex 2} + \text{diagram with } d8 \text{ at crossing} + \dots \quad \frac{1}{\Lambda^4}$$

$$+ \dots$$

($d6^2$ & $d8$ are formally indistinguishable)

Higher dimensional operators can contribute to \mathcal{M}, \mathcal{T} , which appears in denominators $\frac{1}{p^2 - m^2 - i\epsilon \mathcal{T}}$. We don't consider it here (or just expand!)

$$G \sim |M|^2$$

We can truncate σ at \sqrt{s} (collider energy) — $\sqrt{s} \ll \Lambda$

$\frac{1}{\Lambda^2}$ is a very good approximation if $v \ll \Lambda$

$(1+x)^2 \approx 1+2x$ if x is very small!

$\frac{1}{\lambda^4}$ strictly speaking, need to calculate d^8

~~What if Λ is not that large, shall we keep $d\ell^2$?~~

Typically:

If measurement is very precise \Rightarrow can constrain $\Lambda \gg \sqrt{E}$
 \Rightarrow ok to just keep $\frac{1}{\Lambda^2}$ (ideal case!)

What if it's not the case?

typical LHC measurement

Drell-Yan $pp \rightarrow l^+ l^-$

small E ,
large statistics

easier to constrain
 $\Lambda \gg \sqrt{E}$

cut
here
and
throw
away \Rightarrow

(or do something else)

large E , small statistics
can't really tell if a Z' is nearby.
EFT valid?

ok to truncate at $\frac{1}{\Lambda^2}$

(Lepton colliders usually don't have this problem.)

Important exceptions of the $\frac{1}{\Lambda^2}$ power counting:

When SM contribution is absent or strongly suppressed

leading order: $d\sigma^2 \sim \frac{1}{\Lambda^4}$

$SM \cdot d\sigma, SM \cdot d\sigma \ll d\sigma^2 \dots$

- rare process

flavor violation...

proton decay $T_p \sim \frac{m_p^5}{\Lambda^4} \quad \Lambda \gtrsim 10^{15} \text{ GeV}$

- Fermi's theory: Weak interaction

$$T_\mu \sim \frac{m_\mu^5}{\Lambda_{EW}^4} !$$

no interference with QED!

- The interference term with SM is suppressed.

Different helicity amplitudes...

e.g.

$$\sum_{\vec{k}} \bar{f}_L^{\mu} f_L^{\mu}$$

$$\sum_{\mu\nu} \bar{f}_L^{\mu} \sigma^{\mu\nu} f_R$$

no interference in the $m_f \rightarrow 0$ limit!

How SMEFT modifies SM parameters

The SM has a set of free parameters to be fixed by experiments.

$$g \quad g' \quad v \quad \lambda \quad y_t \quad \dots$$

which are related to

$$m_Z, \quad m_W, \quad G_F, \quad \underbrace{\alpha}_{\text{fine structure constant}}, \quad m_h, \quad m_t, \quad \dots$$

$\mu\mu$ decay electron magnetic moment

These relations can be modified by higher dimensional operators!

$$\begin{aligned} \text{e.g. } \mathcal{L} &> y_t \overline{Q}_L^{(3)} t_R \tilde{H} + \frac{C_t}{\Lambda^2} |H|^2 \overline{Q}_L^{(3)} t_R \tilde{H} + \text{h.c.} \\ &= \frac{y_t}{\sqrt{2}} (v+h) \bar{t}_L t_R + \frac{C_t}{\Lambda^2} \frac{(v+h)^3}{2\sqrt{2}} \bar{t}_L t_R + \text{h.c.} \end{aligned}$$

\swarrow 3rd generation

$$\text{SM } C_t = 0: \quad \mathcal{L} = \underbrace{\frac{y_t v}{\sqrt{2}} \bar{t}_L t_R}_{m_t} + \underbrace{\frac{y_t}{\sqrt{2}} h \bar{t}_L t_R}_{g_{htt}} + \text{h.c.}$$

with C_t :

$$\mathcal{L} = \underbrace{\left(\frac{y_t v}{\sqrt{2}} + \frac{C_t v^3}{2\sqrt{2}\Lambda^2} \right)}_{m_t} \bar{t}_L t_R + \underbrace{\left(\frac{y_t}{\sqrt{2}} + \frac{C_t 3v^2}{2\sqrt{2}\Lambda^2} \right)}_{g_{htt}} h \bar{t}_L t_R + h.c. + \dots$$

more h

Question: Does the measurement of m_t gives us a constraint on C_t ?

If $C_t \neq 0$, is m_t not 173 GeV anymore?

No! Because a nonzero C_t only changes the "inferred value" of y_t .

We need 2 measurements to fix 2 parameters.

In other words, C_t changes the relation between m_t & g_{htt}

$$m_t = \frac{y_t v}{\sqrt{2}} + \frac{C_t v^3}{2\sqrt{2}\Lambda^2}$$

$$\frac{y_t}{\sqrt{2}} = \frac{m_t}{v} - \frac{C_t v^2}{2\sqrt{2}\Lambda^2}$$

$$\underline{\underline{g_{htt} = \frac{m_t}{v} + \frac{C_t v^2}{\sqrt{2}\Lambda^2}}}$$

More generally, any operator of the form $|H|^2 \mathcal{O}_{SM}$ can only be probed with the "Higgs particle"!

$$\begin{aligned} \underline{\underline{g_{SM} \mathcal{O}_{SM}}} & \text{ vs. } g_{SM} \mathcal{O}_{SM} + \frac{c}{\Lambda^2} |H|^2 \mathcal{O}_{SM} \\ &= g_{SM} \mathcal{O}_{SM} + \frac{c}{\Lambda^2} \frac{v^2}{2} \mathcal{O}_{SM} + \text{terms with } h \\ &= \left(g_{SM} + \frac{c v^2}{2 \Lambda^2} \right) \mathcal{O}_{SM} + \text{terms with } h \end{aligned}$$

re define $\bar{g} = g_{SM} + \frac{c v^2}{2 \Lambda^2}$

$$= \underline{\underline{\bar{g}}} \mathcal{O}_{SM} + \text{terms with } h$$

(can also be h in the loop)

Similarly, $\mathcal{O}_6 \equiv (H^\dagger H)^3$ can only be probed by measuring the Higgs self coupling!

HW
